Brain MRI

Researchers at Stanford's School of Medicine have discovered that by blocking a molecule found in nerves, they can pause the growth of brain cancer. The protein, called neuroligin-3, plays a role in healthy brain function, but has also been linked to cancer growth.

The researchers bred mice that were genetically altered, and did not produce neuroligin-3. They then implanted human brain tumors in the mice. For the next 4.5 months, the tumors remained, but did not grow. This finding suggests that neuroligin-3, a normally helpful molecule, can be used by tumors to speed cancer growth. However, after 4.5 months, the cancer changed and no longer needed neuroligin-3 to grow.

Clinical trials using neuroligin-3 inhibitors to treat cancer are currently underway.
